Bank Churn Analysis – Project Prerequisites

Objective of the Project:

Analyse the data and bring out few insights on the customer Churn.

It is advantageous for banks to know what leads a client towards the decision to leave the company.

Calculations, measures (DAX):

- **Additional new Tables and Columns:**

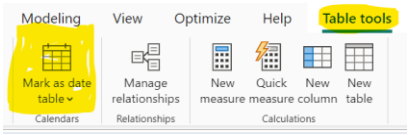
Data has Dates – when data has dates, we must create date table & add required column like year, month, day etc

Always make master date table in that case to perform any time intelligent analysis.

1. **Add new table (date table)**

Date Master Table = CALENDAR (FIRSTDATE (Bank Churn [Bank DOJ]), LASTDATE (Bank Churn [Bank DOJ]))

Note: now mark it as a date table



Add year column, Year = YEAR ('Date Master Table'[Date])

Add Month column, Month = MONTH ('Date Master Table'[Date])

Add month name column, Month Name = FORMAT ('Date Master Table'[Date], "mmm")

Add day column, Day = DAY ('Date Master Table'[Date])

Add Day name column, Day Name = FORMAT ('Date Master Table'[Date],"ddd")

2. **Add Column Credit Type: add column (either add conditional column or write function or dax)**

Credit score:

- Excellent: 800–850
- Very Good: 740–799
- Good: 670–739
- Fair: 580–669
- Poor: 300–579

Credit Score Status = SWITCH(TRUE(), Bank_Churn[CreditScore]>=800 &&
Bank_Churn[CreditScore]<= 850, "Excellent", Bank_Churn[CreditScore] >=740 &&
Bank_Churn[CreditScore] <= 799, "Very Good", Bank_Churn[CreditScore] >=670 &&
Bank_Churn[CreditScore] <= 739 , "Good" , Bank_Churn[CreditScore] >= 580 &&
Bank_Churn[CreditScore] <= 669 , "Fair" , Bank_Churn[CreditScore] >= 300 &&
Bank_Churn[CreditScore]<= 579, "Poor")

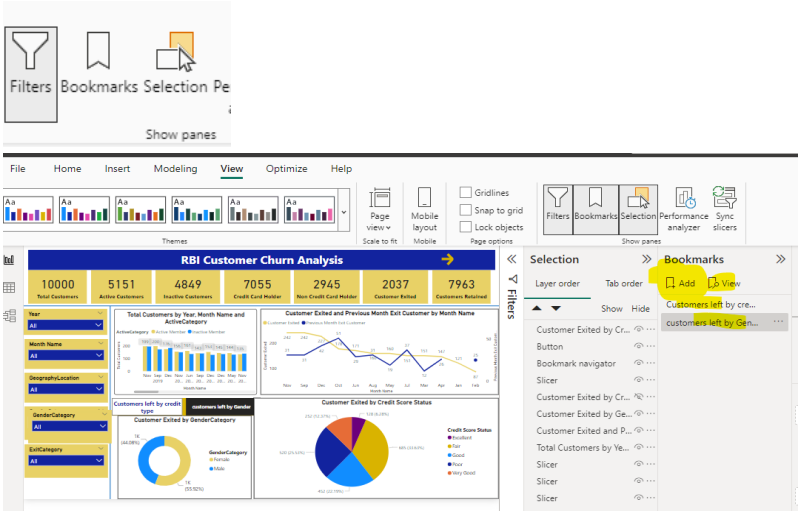
Measures (DAX):

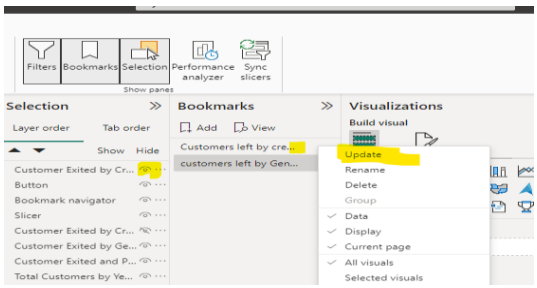
1. Total Customers = count (Bank_Churn[CustomerId]) // This calculates total number of customers //
2. Active Customers = CALCULATE (count (Bank_Churn[CustomerId]), ActiveCustomer[ActiveCategory] = "Active Member")
3. Inactive Customers = [Total Customers]-[Active Customers] // this calculates total number of inactive customers in the organization//
4. Customer Exited = CALCULATE([Total Customers], 'Exit Customer'[ExitCategory] = "Exit") // this calculates no of customers exited from the total number of bank customers//
5. Customers Retained = CALCULATE([Total Customers], 'Exit Customer'[ExitCategory] = "Retain") // this calculates total number of customers retained with the bank //
6. Credit Card Holder = CALCULATE (count(Bank_Churn[CustomerId]), 'Credit Card'[Category] = "credit card holder") // this calculates total number of customers having credit card from the bank//
7. Non Credit Card Holder = calculate (count (Bank_Churn [CustomerId]), 'Credit Card'[Category] = "non credit card holder") //this calculates number of employess doesn not have credit card from the bank//
8. Previous Year Exit Customers = CALCULATE ([Customer Exited], PREVIOUSYEAR ('Date Master Table'[Date])) // this calculates previous year exited customers//
9. Previous Month Exit Customer = calculate ([Customer Exited], PREVIOUSMONTH ('Date Master Table'[Date])) // this calculates total customers exited previous month//
10. Previous Day exit customers = calculate ([Customer Exited], PREVIOUSDAY ('Date Master Table'[Date])) // this calculates previous day exit customers//
11. Churn % =

var CE = [Customer Exited]
var CT = [Total Customers]
var Churnperc =DIVIDE (CE, CT)
RETURN Churnperc   // we have added variable to write dax//

- **Create a relationship (data modeling)**
- **Create a bookmark – Add Button >> or Navigator >> book mark navigator**

When we use book mark? when we overlap tow charts or we want to hide same types of charts, we shuld add bookmarks to save dashboard space.





Conclusion:

Churn prevention allows companies to develop loyalty programs and retention campaigns to keep as many customers as possible.
